A recent study published in the Journal of Applied Psychology found that social media use can negatively impact mental health. Researchers surveyed a large group of participants and found that frequent use of social media was associated with increased levels of anxiety and depression. The study also suggested that the frequency of social media use is a significant predictor of mental health outcomes. 

In addition, the study highlighted the importance of limiting social media use to promote mental well-being. Participants who limited their social media use reported significant improvements in their overall mental health.

The findings of this study provide important insights into the impact of social media on mental health. It is essential for individuals to be aware of these effects and consider limiting their social media use to maintain their mental well-being.
